This study discusses the design and implementation of an Intelligent Computer-Assisted Instruction system for cardioulmonary resuscitation. Utilizing artificial-intelligence techniques, the system combines a learning-while-doing environment with effective guidance of tutorial interactions.

The user's knowledge of CPR procedures is tested at one of three experience levels, utilizing a randomly generated scenario. Using means-ends analysis, the recommended action is determined for each successive state in the scenario. This action is compared with the user's selection. If a difference exists, an hypothesis guides the tutoring module in the selection of a tutoring strategy.

An on-line review of CPR procedures is available, as is a help function to provide direction to the user if needed. At the end of a session, a summary of the user's actions is provided.

ABSTRACT

This study discusses the design and implementation of an Intelligent Computer-Assisted Instruction system for cardiopulmonary resuscitation. Utilizing artificial-intelligence techniques, the system combines a learning-while-doing environment with effective guidance of tutorial interactions.

The user's knowledge of CPR procedures is tested at one of three experience levels, utilizing a randomly generated scenario. Using means-ends analysis, the recommended action is determined for each successive state in the scenario. This action is compared with the user's selection. If a difference exists, an hypothesis is formulated concerning the cause and severity of the difference. This hypothesis guides the tutoring module in the selection of a tutoring strategy.

An on-line review of CPR procedures is available, as is a help function to provide direction to the user if needed. At the end of a session, a summary of the user's actions is provided.

THESIS DISCLAIMER

The reader is cautioned that computer programs developed in this research may not have been exercised for all cases of interest. While every effort has been made, within the time available, to ensure that the programs are free of computational and logic errors, they cannot be considered validated. Any application of these programs without additional verification is at the risk of the user.

TABLE OF CONTENTS

LIST OF FIGURES

ACKNOWLEDGEMENTS

The author wishes to express her gratitude to a number of people who supported this work. To my advisor, **Professor Neil C. Rowe**, who assisted me with the initial idea and direction to start the project, and then stepped back, allowing me the freedom to learn through exploration. This research could not have been completed without his support. His provision of the original version of the *metutor* and the inclusive subroutines enabled this project to go into more depth than could ever have been done otherwise in the limited amount of time available. To **Professor Gordon Bradley** for agreeing "sight unseen" to take the time and effort necessary to be my second reader. Finally, I would like to personally thank my husband, **Fred**, for the understanding, support and patience he provided.

I. INTRODUCTION

Computer-based instruction can dramatically alter the way we learn and teach. A significant advantage of using the computer in the realm of education and training is that it allows for interactive learning for all students. The needs of each student can be met by individualizing the learning experience. In the typical classroom environment there are relatively few opportunities for such interaction between the teacher and the student. Private human tutors can provide this one-on-one interaction; however, they can be cost-prohibitive. The human tutor is also limited in the knowledge they can possess. Computerized instructors, however, can capture the knowledge of many experts and can provide interactive, individualized instruction.

With such enormous potential, one might ask why computers have not had more of an impact in the world of education. Computer-based instruction has been available for many years. The impact of this instructional media, however, has been small. There are many possible reasons for this lack of positive impact. One answer lies in the ability to think. The processes of teaching and learning are fundamentally cognitive activities. To successfully teach, computers must be able to capture the skill of "thinking".

The intent of this thesis is to explore the feasibility of instruction via a "thinking" computer utilizing cardiopulmonary resuscitation (CPR) as the application domain. The reason for this choice of application is its real life applicability to a wide range of students.

A. CPR

The leading cause of death in the United States is cardiovascular disease. It is estimated that a million and a half Americans will have heart attacks each year and one

third of these people will die. This equates to a death rate of 1500 people every day from heart attacks alone. In addition to heart attacks, victims of other situations such as drowning accidents, electrocution, drug overdose and poisoning may also go into cardiac arrest. Most of these victims who die from a cardiovascular failure do so before they ever reach trained medical personnel and emergency equipment. It is therefore the chance bystander who can play a critical role in reducing this death rate by being able to recognize cardiac emergencies, provide proper first aid, and call for medical services.

If a person's heart stops for any reason, cardiopulmonary resuscitation (CPR) must be started immediately. CPR is needed to keep oxygen supplied to the brain and other body organs until more advanced emergency medical treatment is available. Knowing how to immediately provide correct CPR procedures when confronted with an emergency can mean the difference between life and death for many victims. [Ref. 1]

Formal CPR classes are an important method for teaching these correct procedures. Demonstrated public interest in learning CPR is high and more people are being trained in the correct procedures. However, in most cases when a cardiac arrest occurs, CPR is not started by bystanders, but is delayed until trained medical personnel arrive on the scene. This suggests that even people trained in correct CPR procedures may lack the confidence to use their skills in an emergency. [Ref. 2]

It is the intent of this thesis to provide an intelligent computer-assisted instruction system, not to replace currently available CPR courses, but to supplement them. This one-on-one tutoring is designed to raise the confidence level of the user so that when confronted with an emergency, critical minutes will not be lost. An intelligent computer-assisted instruction system can offer several unique advantages over the more traditional classroom approaches. The 24-hour availability of such a system affords the user the scheduling flexibility of receiving training at their convenience. The system,

unlike a human tutor or instructor, never loses patience with the student and can provide undivided attention at all times. The system also has the capability to test the student on unusual occurrences, many of which are more likely to occur when the student is allowed to pursue their own ideas rather than be streamlined through the correct or "logical" sequence of actions.

B. METHODOLOGY

In designing and implementing a computerized instruction system for CPR, henceforth referred to as the CPR Tutor, artificial intelligence (AI) techniques implemented in the Prolog programming language were utilized. A computer program such as this is referred to as intelligent computer-assisted instruction (ICAI) system or an intelligent tutoring system (ITS). Both terms will be used interchangeably throughout this study. The development of such a system focuses primarily on the problems of knowledge representation, student misconceptions, and inferencing [Ref. 3].

The basic components of the CPR Tutor are the student model, the expert module, the tutor module, and the user interface. The student model represents what the student does or does not know. The comparison of the student model with the expert module generates discrepancies that are analyzed by the tutor. The tutor provides appropriate feedback and updates the student model accordingly. The user interface serves as a buffer between the user and the CPR Tutor.

Programmed with information provided by the American Red Cross [Ref. 1], the CPR Tutor can randomly generate various emergency situations. The situation is displayed to the user as a list of facts. The CPR Tutor can prompt the user for an action in the stated situation, require a more detailed description of the action from the user, or provide assistance to the user in selecting the most correct action. After the user has entered their action selection in the given situation, the CPR Tutor will compare the

user's choice with that of the expert module. Based on this comparison, the user gets immediate results of their action in the form of a positive acknowledgement for the preferred response, a warning statement of varying severity for an incorrect response, or a message indicating the users response differs from the expert but the system will pursue the user's approach to the situation.

The CPR Tutor was organized into four primary files: *cpr, mecpr, metutor,* and *utilities.* The *cpr, mecpr,* and a portion of the *utilities* files were developed by the author to provide the CPR domain knowledge as well as the overall structure of the user interface. This Prolog code was developed to operate in conjunction with a generic means-ends analysis tutoring system, *metutor,* developed by Professor Rowe of the Naval Postgraduate School. Minor modifications were made to the *metutor* file to accommodate a menu-driven user interface and to include a limited amount of CPR domain specific tutorial responses in addition to the general tutoring strategies already present.

C. PREVIEW

Chapter II provides background information on CPR and the method by which it is currently taught by the American Red Cross.[1] Also included is a description of the the training format used in the American Red Cross Adult CPR course. Chapter III provides a background on computer-assisted instruction (CAI). This includes a review of computer-based instruction (CBI) and intelligent computer-assisted instruction (ICAI); these two are compared and contrasted, and specific applications of each are introduced. Chapter IV discusses the actual design and implementation of CPR Tutor. Chapter V discusses use of the CPR Tutor. Issues of expandability and portability of the system are addressed, as well as limitations and benefits of the system. Chapter VI is the summary

---

[1]See References 1 and 2 for a detailed description of these procedures.

and provides a final discussion of the research questions. Appendices A through C present user sessions. Demonstrations are offered at each of the three user levels: novice, intermediate, and advanced. Appendix D contains the Prolog source code for CPR Tutor developed by the author. Appendix E contains the Prolog source code developed by Professor Rowe.

II. OVERVIEW OF COMPUTER-ASSISTED INSTRUCTION

A. BACKGROUND

The use of the computer for teaching dates back to the late 1950s. The most common label for computer assistance in teaching and in the learning process is CAI, referring to computer-assisted instruction or, equally commonly, computer-aided instruction. CBI, computer-based instruction, is also used in reference to this same instruction. Other labels which are used include CAL, where "learning" replaces "instruction" and thus places a greater emphasis on the activities initiated by the learner than on the instructional materials created by the teacher-author. Replacing "instruction" with "education" as in CAE or CBE, computer-based education, similarly shifts the implication to infer a wider variety of computer uses, including administrative data processing and materials production as well as student use of computers. If emphasis is to be placed on the computer assisting the teacher in managing instruction, computer-managed instruction, CMI, is the more appropriate label. [Ref. 4]

Intelligent computer-assisted instruction, ICAI, refers to the more recent form of computer delivered instruction. ICAI utilizes artificial intelligence technology applied to instruction. To provide greater distinction and differentiation between this more recent approach and the older, more traditional ones, the descriptive phrases ICAI and CBI will be used throughout the remainder of this study.

B. COMPUTER-BASED INSTRUCTION

Traditional computer-based instructional systems tend to be designed and implemented by educational psychologists or technologists. Designed to solve practical problems by applying computer technology, a basic theme of CBI is that "the computer is

neither instruction nor a method of instruction; it is merely a vehicle of instruction". [Ref. 5] Although many different types of instructional strategies have been applied in CBI, the most prevalent have been based on the common approaches practiced in schools and training environments. The basic principle being that the instructor should successfully communicate their knowledge to the student to achieve the objectives within the imposed constraints. The success of the system is primarily determined by its degree of instructional effectiveness and efficiency. This teacher-centered approach requires the student to first understand the teacher's instruction and reinforce this understanding through practice. In this approach, the student has little or no initiative in the instructional process [Ref.3:pp.24-29].

The early CBI systems were developed primarily as a supplement to the principal instructional process. Taking the form of programmed-instruction paradigms, the formats of these systems were either electronic "page turners", which simply printed prepared text, or drill-and-practice, which printed problems and utilized prestored answers and remedial comments to respond to the student's solution [Ref.6:p.225]. As CBI has since evolved to become a main instructional delivery system, as opposed to merely a supplemental system, the format has diversified. In addition to the drill-and-practice approach, CBI formats now include tutorial, games, and simulations.

C. ICAI SYSTEMS

ICAI is a more recent form of computer-assisted instruction. Evolving from the field of computer science, it is an example of the application of artificial-intelligence technology to instruction. The basic philosophies underlying the structures and development processes are therefore fundamentally different from traditional CBI. The focus of ICAI projects has been on the technical and instructional aspects of the system as opposed to the domain features. Many ICAI projects have, however, also sought to

better understand the cognitive processes involved in learning and teaching. It can thus be asserted that ICAI programs actually lie at the intersection of computer science, cognitive psychology, and educational research. [Ref. 3]

1. Structural Methodology

Although ICAI programs often bear little outward resemblance to each other, most of these systems deal with similar issues and contain similar functional components. A typical ICAI system contains three primary components: the representation of knowledge, the provision of instruction, and the modeling of learning behavior. These components are commonly referred to as the expert module, the tutor module, and the student model respectively. In addition to these three components, a student interface is also necessary. Figure 2.1 depicts a generalization of the components in an ICAI system [Ref. 3].

a. Expert Module

The expert module is the encapsulation of the domain expert, containing the knowledge that the system is attempting to impart to the student. It is this module that generates "problems" and is used to evaluate the correctness of the student response. If a fully developed ICAI system is to be maximally effective, several experts in the domain should be members of the development team, to overcome the incomplete knowledge or conceptual vacuums that are often present in a sole expert. The domain knowledge found in textbooks is also often incomplete as well as idealized and, as such, is inappropriate as the primary knowledge source for a truly effective and operational ICAI system. [Ref. 7]

b. Tutor Module

A distinguishing feature of ICAI systems is the separation of the expert knowledge from the teaching strategies. An AI system that is an expert in a particular domain is not necessarily an expert teacher of the same domain. The acquisition of

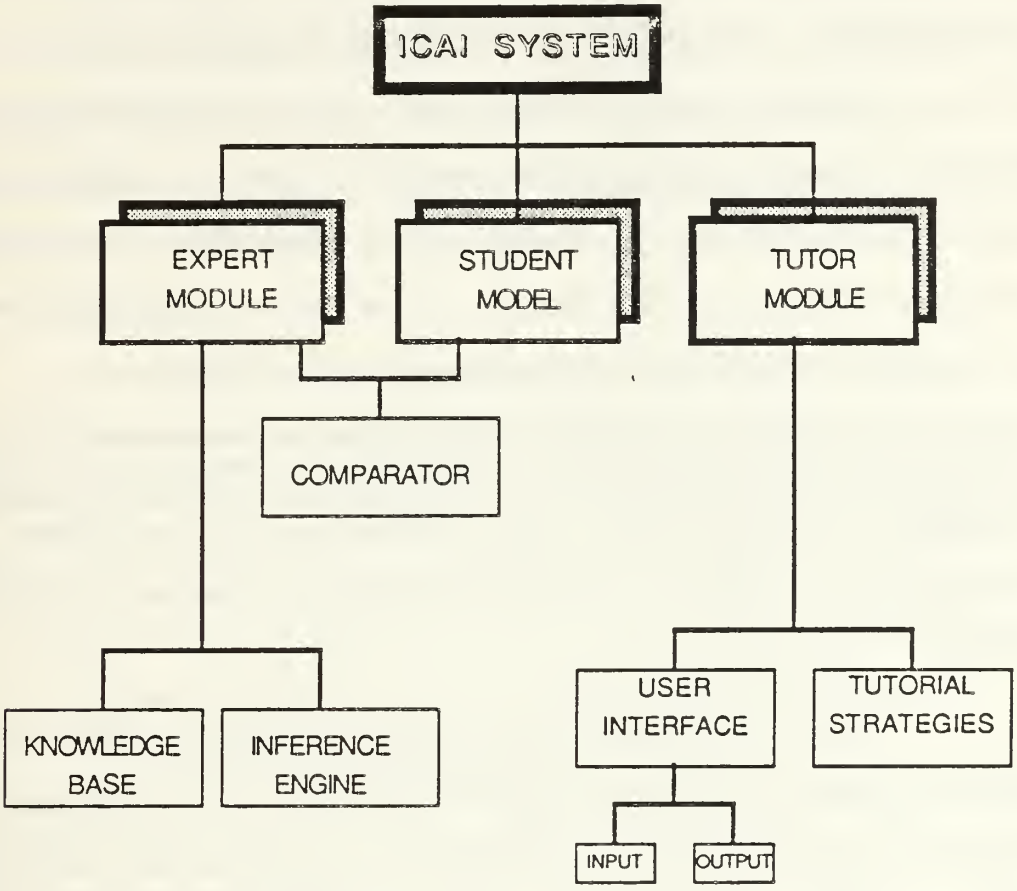

Figure 2.1 ICAI System Components

sufficient and correct teaching expertise has been a long-term problem for builders of tutoring systems [Ref. 7]. Multiple teaching strategies exist and no single strategy is appropriate for every domain. Each state in the domain, as well as each student, must be assessed if an appropriate teaching strategies are to be employed. It is therefore the task of the teaching expert, the tutor module, to choose the next strategy. This includes

providing diagnostics, questioning the student further or in more detail, and presenting new information. A central issue in the design of this module is the appropriateness of providing immediate responses to the student's action as opposed to temporarily allowing the student to continue down an incorrect path without interruption.

ICAI systems mainly use two types of instructional strategies although many other strategies do exist and have been used. The two basic classifications are the Socratic, tutorial method and the coaching method. The Socratic method involves questioning the student and guiding them through the process of debugging their own misconceptions. Wenger [Ref.8:p.39] summarizes this method by stating:

> In the Socratic method, the tutor does not teach a subject by direct exposition, but leads the student by successive questions to formulate general principle on the basis of individual cases, to examine the validity of her own hypothesis, to discover contradictions, and finally to extract correct inferences from the facts she knows.

The student is thus encouraged to reason about what they know and thereby modify their conceptions.

The goal of coaching is to encourage the acquisition of skills and general problem-solving abilities by engaging the student in activities such as computer games. The immediate aim of the student is to have fun; skill acquisition and learning is, by design, an indirect consequence. Tutoring comes about through appropriate interruptions by the coach that offer new information or suggest new strategies. Primary challenges in using this instructional method lie in being able to "observe" the student's play of the game, determining what skills or knowledge the student is likely to acquire based on their playing skills, and judging effective times and means for intercession. [Ref.6:pp.233-235]

c. Student Model

The primary focus of the student model is to represent what the student does and does not know, or the student's understanding of the material being taught. The

purpose of modeling the student is to enable specific assessments to be made of the student's knowledge of the domain and to hypothesize about their misconceptions and the reasoning strategies they employed. The tutor module is thereby able to point out misconceptions and make suggestions. The model is generally constructed by comparing the student's response in a given state to that of the expert in the same state, the expert being contained in the expert module. This techniques is referred to as the "overlay model." [Ref.3:p.17]

2. Applications

The impetus of the development of ICAI systems was **SCHOLAR** , a Socratic tutor designed to teach students about South American geography. It was the pioneering effort in the development of tutorial dialogues capable of handling unanticipated student questions and of generating instructional materials in varying levels for the student. Developed in the 1970, SCHOLAR is on of the earliest ICAI systems and, as such, was instrumental in setting the basic themes and goals for the field. [Refs.6, 8]

An extension of SCHOLAR, **WHY** tutors students in the causes of rainfall. Also implementing the Socratic tutoring method, WHY made the effort to describe the global strategies used by human tutors to guide the tutorial dialogue. Although it remained primarily theoretical, WHY represented the first attempt at capturing a complete tutorial strategy as complex as the Socratic method in a concise, rule-based computational model. [Refs.6, 8]

SOPHIE was developed to explore the student initiative during the tutorial interaction. The pedagogical purpose in SOPHIE was to provide a reactive learning environment in which the student could try out their own ideas, have them critiqued, and receive advice. Set in the domain of troubleshooting electronic circuits, this program allowed the student the chance to apply their theoretical knowledge of electronic laws in

a simulated electronics laboratory. Students were challenged to explore their own ideas and to come up with conjectures or hypotheses about troubleshooting strategies for electronic circuits. The role of the expert was to provide detailed feedback as to the logical validity of their proposed solutions. With roots going back to the early 1970s, SOPHIE went through three successive phases spanning more than five years. The research it spawned continues today. [Refs.8, 9]

Initiated in the context of SOPHIE, which was originally meant to include a troubleshooting coach, **WEST** was the first ICAI system to use the coaching strategy. The domain of electronics was viewed as too complex for a first computer-based investigation into the strategy of coaching, hence WEST was developed to coach students in elementary arithmetic. Another ICAI system that used the coaching strategy was **WUMPUS**, which challenged the student in the domains of logic, probability, decision theory and geometry. [Refs.6, 9]

GUIDON was a program developed to teach diagnostic problem-solving. Its mixed-initiative dialogue differs from the other ICAI systems listed above in its use of prolonged, structural teaching. It went beyond simply responding to the student's last move, the methodology used in WEST and WUMPUS, and the repetitive questioning and answering technique used in SCHOLAR and WHY. The uniqueness of GUIDON, however, was in its attempt to turn an existing expert system, MYCIN, into an intelligent tutor. GUIDON demonstrated the inappropriateness of using just an expert system's knowledge base as the expert module of an ICAI system without supplementation to help explain and organize the knowledge in the process of teaching. [Refs.6, 9]

While a complete ICAI system has the three primary components, not all systems do. **PROUST** and **STEAMER** are two such examples: they do not contain tutoring functions. PROUST is a knowledge-based system to find nonsyntactic bugs in

Pascal programs written by beginning programmers. The key idea of STEAMER is the conception of an interactive inspectable simulation of a steam propulsion system. Its primary concern is how people understand and reason about complex systems as well as how interactive graphical interfaces might support the development of useful mental models. Started in the late 1970s, STEAMER is not yet an operational system. However, it is considered of significant importance in the field of ICAI because it called for a very careful look at what aspects of AI technology are actually ready for application in the design and implementation of an instructional system. [Ref. 3]

OBIE-1:KNOBE was the first generic system to enable the construction of realistic, dynamic representations of real devices. Intelligent simulations previous to it were not generalized. They were specifically designed and built with only the immediate subject domain in mind. [Ref. 10]

One system which has been fully implemented, tested and is in use, although still being augmented based on formal student evaluations, in nearly sixty industrial sites across the United States is **RBT**, Recovery Boiler Tutor. The tutor is based on a mathematical formulation of a type of boiler found in paper mills. It provides an interactive simulation in which emergencies can result from inappropriate student responses. An unusual point about this system is its use of Fortran and C as the implementation languages. [Ref. 7]

D. COMPARISON AND CONTRAST OF CBI AND ICAI

1. Focus

Traditional CBI has been developed primarily by educational psychologists and technologists. The role of the computer has generally been that of a vehicle for efficient implementation. As an older, more established field, textbooks are available which suggest detailed guidelines, procedures and principles which should be followed in

designing a CBI system. The overall goal of a CBI system is thus the usability of an effective and efficient system [Ref. 5].

ICAI, in contrast, has primarily been a computer science initiative in the application of AI technology in the educational/instructional process. The focus has been on the technical aspects such as knowledge representation techniques, inferencing mechanisms, natural language dialogues, etc.

2. Subject Matter Domain

CBI systems have been developed for a wide range of subject areas, including math and sciences as well as the arts. The subject matter is, in fact, virtually unlimited. The application domain of ICAI systems have generally been limited to subject areas which are themselves relatively well-structured. With the emphasis being on the AI technology rather than a specific domain, subject matter areas have primarily been selected due to their appropriateness for the AI technique being researched. The emphasis has thus been more on the process itself, rather than the end result. [Ref.3:p.28]

3. Format

The early CBI programs were used generally as a supplement to the principal instructional method. The basic format was drill and practice, serving to reinforce the material that was previously presented by the instructor. CBI has since evolved into a main instructional delivery system and the format has correspondingly diversified. Common CBI formats now include intrinsic and extrinsic games; physical, situational, and process simulations; and tutorials in addition to drill and practice. [Ref.3:p.27]

ICAI does not tend to use the simulation nor the drill and practice formats. Instead, these systems tend to fall into the category of either a tutorial or a game. Although both CBI and ICAI systems use these latter two formats, the methodology and

purpose are different. In a CBI tutorial, the questions are used to reinforce the material that has been provided by computer-based instruction. These questions are always initiated by the system, answered by the student, and are directly related to the presented material. The computer does not "know" the subject matter but merely presents blocks of text. Questions are posed to the student based on a predetermined algorithmic process. ICAI systems, on the other hand, take a more dynamic approach. Attempting to carry on a series of question and answer exchanges, many ICAI systems can carry on a natural language, or pseudo-natural language, dialogue with the student. Not only does the system ask questions of the student, but the student is also able to direct questions to the system. In addition to allowing greater flexibility, ICAI systems utilize these question-and-answer exchanges to make a determination of what the student understands and direct the instructional process accordingly. [Ref.3:pp.24-27]

Intrinsic games are used in CBI as a means of teaching gaming rules and/or skills. Extrinsic games are used primarily to maintain the motivation of the student. The use of games in ICAI systems is similar to the use of extrinsic games in CBI systems, the purpose being to provide a "reactive learning environment". The difference is that in ICAI systems, students are expected to develop a higher level of knowledge. The games are generally designed to allow the student the ability to explore and test their own ideas and thus, control the instructional process to a greater degree. [Ref.3:pp.27-28]

4. System Design Structure

Traditional CBI structure is frame-oriented. It is organized as a file of screens to be presented to the student. A more dynamic approach is taken by an ICAI system. The design structure is the combination of a knowledge database with a transaction series for using the database [Ref. 11]. Thus, a distinguishing feature of ICAI systems is the separation of the teaching strategy(s) from the subject expertise to be taught [Ref. 6].

5. Development Process

The development of most CBI programs has utilized a systems approach [Ref. 5]. This approach requires several steps of procedural activities. Included in this process is a needs analysis, followed by the design and development as well as the implementation. Evaluations are conducted throughout the various stages.

No such generalized procedure can describe the development of ICAI systems. In addition to the fact that very few ICAI systems have been chronologically or systematically documented, the inherent difference in goals plays a significant role. The development of each ICAI system has been guided by the specific goals and skills of the individual researchers as well as the actual characteristics of the application domain. The development process has, therefore, varied among the various ICAI projects.

In comparing the development time required for CBI and ICAI, it is estimated that the first hour of a CBI system requires approximately two hundred hours of programmer preparation, an amount probably exceeded by the preparation time required for an ICAI system. Each additional hour of instruction in a CBI system requires an additional two hundred hours of programmer preparation. ICAI systems, by comparison, are designed to utilize a single piece of knowledge in many ways. Therefore, each additional hour of instruction can be expected to require relatively less programmer preparation time. [Ref. 7]

6. Hardware and Software

A driving force in the development of computer delivered instruction has always been the evolution of computer technology. CBI systems of the 1960s and 1970s utilized special computer systems developed primarily for CBI, such as PLATO, TICCIT, and IBM 1500. Each of these early systems also has their own programming language specifically designed for authoring CBI systems. These were, respectively,

TUTOR, APT/TAL and Coursewriter. These systems, with the exception of IBM 1500, are still in use today. With much lower associated costs, microcomputers, however, have become the most commonly used system for both development and implementation. In addition to the system-specific languages, three other levels of software are currently used. These are: 1) general-purpose languages such a Pascal, C, FORTRAN and BASIC, 2) system-independent CBI languages, and 3) authoring systems that provide facilities, without requiring programming skills to develop CBI courses of instruction. Although exceptions exist, ICAI systems, with their emphasis on the application of AI technology, have primarily been developed on special AI hardware or computers supporting an AI language. The software has been, for the most part, limited to LISP and Prolog. [Ref.3:pp.29-30]

III. OVERVIEW OF CPR

It is estimated that one out of every five Americans has some form of cardiovascular disease and one out of every two people will die from a heart attack or a related disease. As such, it is the leading cause of death in the United States. It is estimated that forty percent of cardiac arrest victims could be saved if CPR was immediately provided and the initiation of advanced life support measures by qualified medical personnel followed within eight to ten minutes. [Ref. 1]

A. PURPOSE

Cardiopulmonary resuscitation is the combination of artificial respiration and manual artificial circulation. It is a means of supplying oxygen to the body when a person's heart has stopped. By breathing oxygen into the victim's lungs, oxidated blood can then be circulated through the victim's body by manually compressing and releasing on the lower half of the sternum. CPR does not "revive" victims nor does it restart the heart. CPR does, however, provide critical life-sustaining oxygen to the brain and other body organs until advanced life support systems provided by professional medical personnel can get the heart restarted. Thus, the twofold purpose of CPR is 1) keeping the lungs supplied with oxygen when breathing has stopped and 2) keeping blood circulating and carrying oxygen to the brain, heart, and other body parts. [Ref. 1]

B. PROCEDURES

Cardiopulmonary resuscitation is a combination of rescue breathing in which oxygen is artificially breathed into the victim and manual chest compressions which keep oxygen-carrying blood flowing through the blood vessels. The external cardiac compressions consist of the application of rhythmic pressure over the lower half of the

sternum, compressing the heart and producing a pulsatile artificial circulation. Artificial ventilation achieved through rescue breathing must always be provided in conjunction with external cardiac compressions. [Ref. 1]

To achieve maximum effectiveness in the performance of CPR, actions by the rescuer must be deliberate and precise. Attention to detail is vital. The order of actions and the number of repetitions is not arbitrary. The following paragraphs list the actions, henceforth referred to as operators, which are the basics of CPR. Figures 3.1 and 3.2 summarize the sequencing of actions.

Check unconsciousness is the first operator recommended in the process of providing CPR. The determination of consciousness or unconsciousness will dictate which further actions may be required. Although a conscious person may require first aid, CPR is not applicable. If the person should lose consciousness and no pulse nor breathing is observed, CPR should be initiated immediately.

Yell for help is performed to beckon assistance. If assistance is available, they can be instructed to phone emergency medical services. If assistance is not available, it will be necessary for the rescuer to perform CPR for at least one minute and then temporarily cease CPR to contact the paramedics personally. This operator is ideally performed after unconsciousness is checked. However, it can also be correctly applied prior to the check unconsciousness operator.

Position victim is a prerequisite to to the proper performance of CPR. It is impossible to accurately judge whether or not a victim is breathing unless they are on their back. Chest compressions also require the victim to be on their back.

For breaths provided by the resuer to be effective, the airway must be open. Therefore, it is necessary for the rescuer to perform the operator **open airway.**

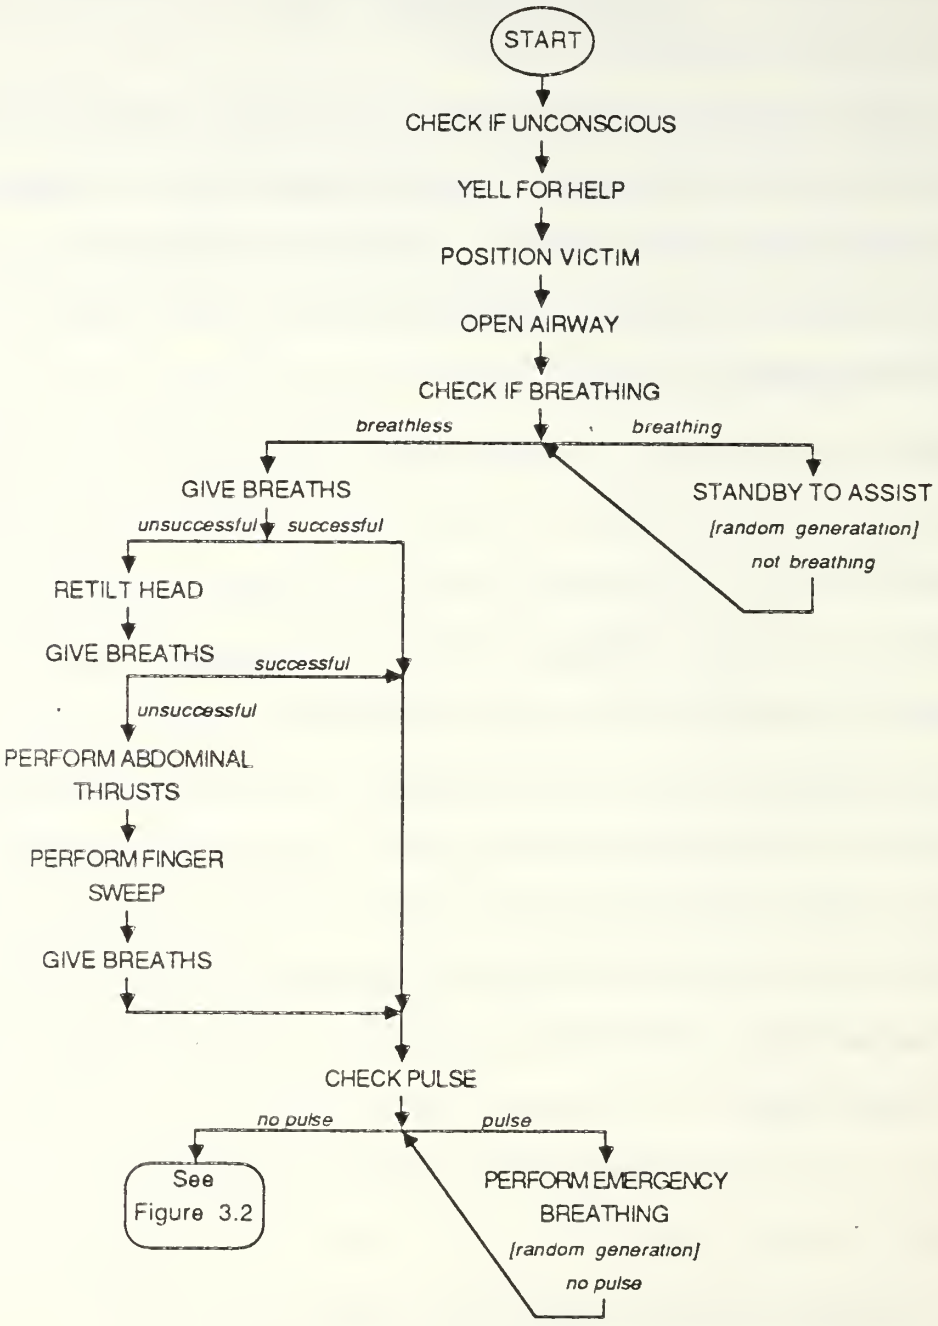

Figure 3.1 CPR Procedural Flowchart - Part One

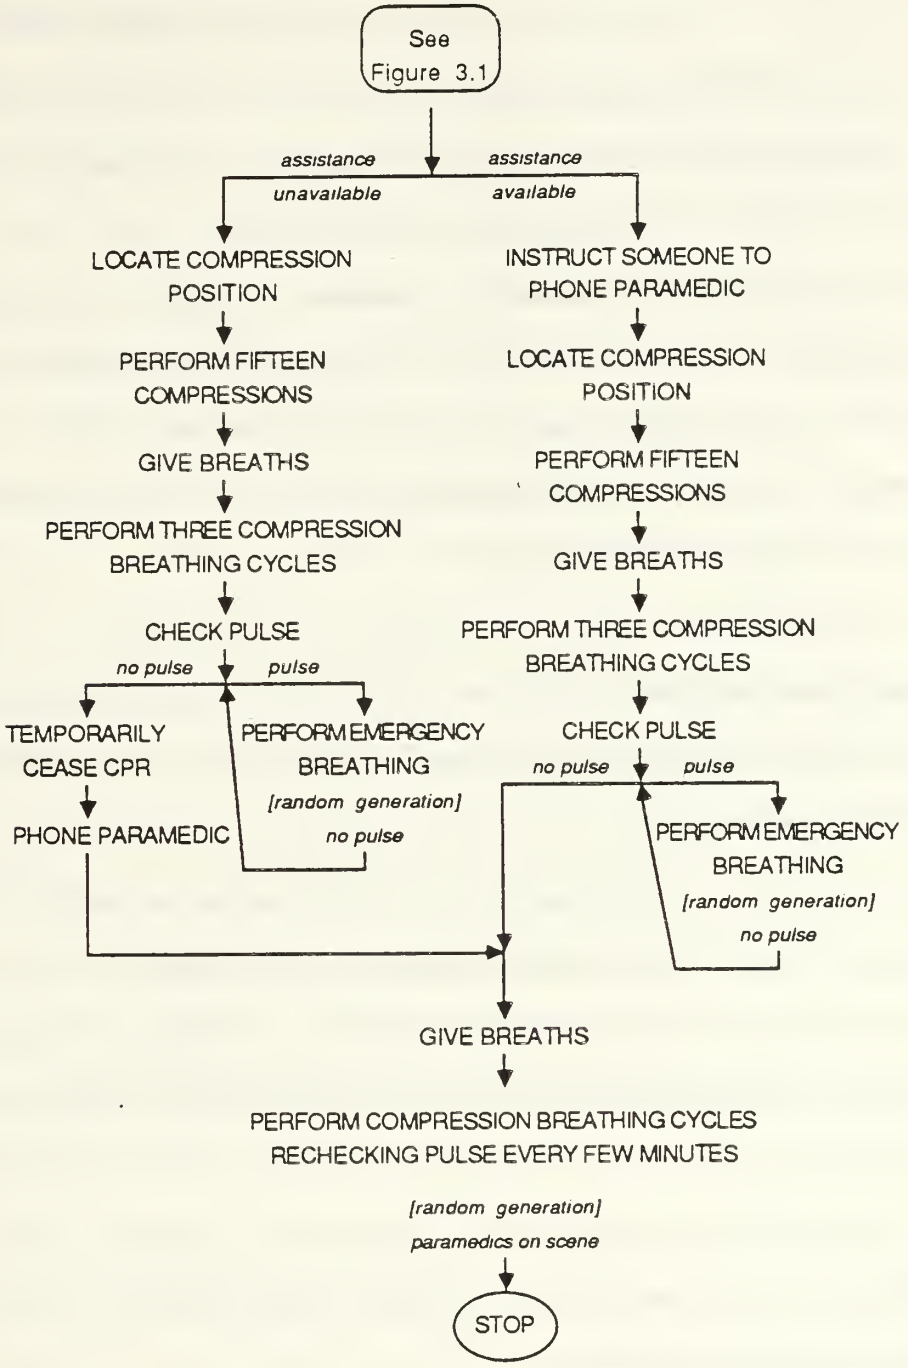

Figure 3.2 CPR Procedural Flowchart - Part Two

If a person is breathing, CPR is never applicable. In fact, performing chest compressions on a breathing victim may result in serious injuries. Prior to performing CPR on an unconscious person it is therefore necessary to **check for breathing.**

Standby to assist is not an actual CPR operator. It is performed only as a default. It is used when the victim is breathing and is not bleeding.

The operator **give two breaths** is performed multiple times throughout the CPR process. When breathing ceases, artificial breathing by the rescuer is necessary to maintain a flow of oxygen within the victim's body. Oxygen is forced through the body by compressions performed by the resuer on the stemum. To be effective, the victim's airway must be open and unobstructed.

If breaths into the victim do not successfully go in, it is necessary for the rescuer to use the operator **retilt head.** This is the first action to be taken in attempt to successfully enable oxygen to enter the victim's body. It is followed by a second attempt of the give two breaths operator.

In the event of an obstructed airway, **perform abdominal thrusts** is an operator to dislodge a foreign object. Abdominal thrusts are performed after first retilting the victim's head and a second attempt to provide two breaths is unsuccessful. After performing abdominal thrusts, the object, if present, should be removed by performing a finger sweep.

Perform finger sweep is conducted following the abdominal thrusts. The intent is to dislodge a possible object which may be blocking the victim's airway and preventing oxygen from entering the body.

The operator **check pulse** is a necessary step in the CPR procedure because performing chest compressions on a victim who has a pulse can result in serious medical complications. Emergency breathing should be provided to a victim who has a pulse but

is not breathing. For the victim who is not breathing and who does not have a pulse, CPR procedures should be initiated immediately.

When the heart ceases beating, blood no longer circulates, which deprives the body of oxygen. The victim will stop breathing due to a shutdown of the respiratory system. A person with no pulse will thus not be breathing. However, a person who is not breathing may have a pulse. In this case, it is necessary for the rescuer to **perform emergency breathing.** This is a high level operator which actually consists of the repetitive use of give two breaths operator as well as the recheck pulse operator. This cycle is performed until such time as the victim is breathing on their own or their pulse has also stopped, in which case chest compressions associated with CPR become applicable.

One of the two options for contacting professional medical services is **instruct someone to phone paramedic.** If assistance is available, they should be instructed to contact professional emergency medical services after the resuer has determined the vital signs of the victim.

The second option for contacting professional medical services is for the rescuer themselves to **phone paramedic.** If assistance is not available, it is necessary for the rescuer to first perform CPR for at least one minute and then temporarily cease CPR to contact professional emergency medical services. CPR should then be immediately resumed.

Temporarily cease CPR is not a CPR operator per se. It is performed by the rescuer if assistance is not available and they must personally contact professional medical services. As such, it is only performed in conjunction with the phone paramedic operator.

Locate compression position is a prerequisite to the performance of chest compressions. Not locating the correct position could nullify the significance of performing chest compressions.

Perform fifteen compressions causes the the oxygen the rescuer has breathed into the victim to be forced throughout the body. Prior to performing these compressions, the correct compression position must be located.

The essence of CPR is **perform compression/breathing cycles.** This consists of the rescuer providing breaths to the victim, followed by chest compressions to force the oxygen through the victim's body. Chest compressions should never be performed on a person with a pulse. Therefore, periodic checks for a pulse should be performed. This higher level operator is used in the latter portion of the CPR procedure. It's used in lieu of multiple instantiations of the two low level operators, perform fifteen compressions and give two breaths.

Recheck pulse is performed to ensure chest compressions are not performed on a victim with a pulse. If compressions are performed on a person with a pulse, serious medical complications may arise.

Stop bleeding is not actually a CPR operator, but is included to provide more realism. It is important for a rescuer to realize that CPR always takes precedence over other first aid actions. It is performed only if the victim is bleeding and is also breathing. The rescuer must be primarily concerned with the pulse and breathing of the victim. Bleeding must be ignored if the victim has no pulse rate and/or is not breathing.

C. TRAINING PROGRAMS

The American Red Cross Adult CPR course was designed for the general public. Anyone thirteen years of age or older or who has completed the seventh grade and expresses an interest in learning CPR procedures is encouraged to take the course. The

duration of the course is six hours and can be taught in either one session or split into two three hour sessions. To maintain Red Cross certification, retraining is required on an annual basis. The course includes three components: a student workbook, six films, and practice sessions. Participants read the workbook and answer review questions at the end of each chapter. Films are interspersed throughout the course. They include real-life emergencies and show demonstrations of the first aid skills being taught. Practice sessions and skill tests allow students to actually practice the learned skills. Each student must also pass a written test to receive a course completion certificate. [Ref. 1]

IV. CPR TRAINING: AN ICAI APPROACH

A. SYSTEMS ORGANIZATION

The CPR Tutor is an ICAI system which utilizes the Socratic tutoring methodology. It was developed and implemented on a Digital Equipment Corporation VAX minicomputer using the C-Prolog language. The design is based on the interaction of the four primary modules discussed in chapter two, section C. These are:

1. Expert Module
2. Tutor Module
3. Student Model
4. User Interface

Figure 4.1 illustrates the interrelationships of these modules. Also shown is their file location in the CPR Tutor program.[2]

B. EXPERT MODULE

The expert module of an ICAI system consists of two major parts. These are the inference engine and the knowledge base.

1. Inference Engine

The inference engine used in the CPR Tutor prototype is an application of **means-ends analysis**, a classic technique used to solve search problems by abstraction. Using double recursion to decompose the CPR procedure, means-ends analysis reasons top-down from abstract goals, with the "ends justifying the means." The means-ends analysis Prolog program used in the CPR Tutor prototype was written by Professor

---

[2]See Appendices D and E for a listing of these files.

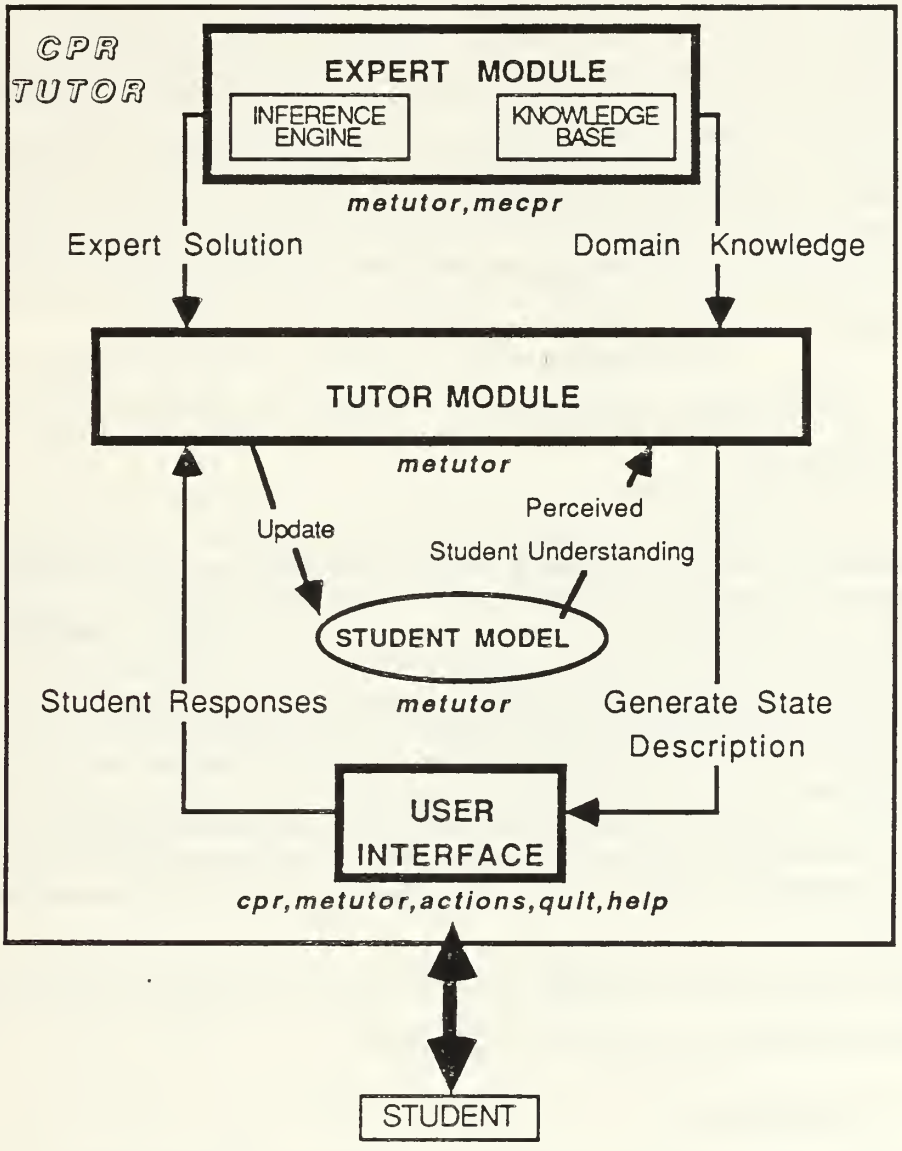

Figure 4.1 CPR Tutor Structural Model

Rowe. The top-level rule is a recursive **means-ends** predicate of four arguments: **State, Goal, Oplist** and **Goalstate.** The **State** is a complete list of the facts which are true in a state. In the CPR Tutor prototype the single fact *person-collapsed* was chosen to be the starting state. The **Goal** is a list of facts that are required to be true in the goal state (or partial description of the goal state). The **Goal** chosen for the CPR application was *victim is breathing and_or paramedic is on scene.* The **Oplist** is the list of operators that are required to reach the goal state from the starting state. This list is always initially the same. However, it changes as random substitutions of facts are made. The **Goalstate** is the complete list of facts which are true in the goal state. [Ref. 12]

Professor Rowe [Ref.12:p.270] describes the operation of the means-ends program as follows:

> This recursive program has a single basis step (the first line), which says we don't need any operators to solve a problem in which the starting state includes all the goal facts. The rest of the lines are a single induction step, which...has two recursive calls: the first for the preconditions, the second for the postconditions. The lines say to first compute the list of facts different between **State** and **Goal**, and find a recommended operator for some subset of those facts. Look up the preconditions of the operator and recursively call **means-ends** to figure how to satisfy them. Then look up the deletion postconditions and delete them from the final state resulting from the precondition recursion; look up the addition postconditions, and add them to that state. Now we have the state after application of the original recommended operator. So recursively call **means-ends** to figure how to get from here to the original goal. The final operator list for the whole problem is the appending together of the precondition-recursion operator list.

A complete listing of this unchanged program used as the inference engine in the expert module in CPR Tutor is contained in Appendix E.

2. Knowledge Base

Cardiopulmonary resuscitation is a combination of artificial respiration and manual artificial circulation. These two primary actions can be further decomposed into a series of basic sub-actions, the application of which is not arbitrarily ordered. CPR can be considered a procedural evolution from a starting state to a goal state via intermediary states. Because most of these abstracted states are strongly ordered in the CPR process,

there exists nearly a unique recommended solution path, i.e., recommended application of operators from the start state to the goal state. Deviations from this path in the means-ends program can occur only as a result of a random side effect. One example of such a random change in state is a deletion of the fact *victim is breathing* and the addition of the fact *victim is not breathing*. When the victim is breathing no action, other than to standby to assist, is required of the rescuer. However, it is necessary that the rescuer be knowledgeable of what actions are necessary should the victim cease breathing. The random generation indicated above is designed to test the student's knowledge of what to do in this event and prompts the continuance of the tutoring session.

The knowledge-base operators must be clearly identifiable and there must exist a recommended ordering among them. This recommended order, however, need not be predetermined by a list. Instead, each operator has one or more associated **recommended** predicates:

recommended([<resultant-fact>], <operator>).

which indicate the facts that application of the operator will help achieve.

Also associated with each operator must be a **precondition** fact and a **postcondition** fact.[3] Preconditions are the prerequisites required for the application of the operator. Postconditions are the changes that occur when an operator is applied.

Two-argument facts identify preconditions. The first argument is the operator and the second argument is the list of applicable prerequisites for the application of the

[3]The recommended, precondition, and postcondition predicates are necessary input to Professor Rowe's means-ends analysis program which serves as the expert module's inference engine. As such, the formats of each are predetermined.

specified operator. The format for precondition facts is as follows:

precondition(<operator>,[<prereq-fact1>,<prereq-fact2>,...]).

If no precondition exists for an operator, i.e., it can be applied at any time, the null condition, [], is used. The precondition facts used in the CPR Tutor prototype are displayed in Figure 4.2.[4]

Postconditions can either add new facts, delete facts, do both, or do neither. Two kinds of postconditions are thus associated with each operator, addpostconditions

---

```
precondition(check_if_breathing,
    [on_back(victim), open(airway), not(breathing(victim)), not(stopped_breathing)]).
precondition(recheck_pulse,
    [unconscious(victim), performed('compression breathing cycles')]).
precondition(open_airway, [on_back(victim), unconscious(victim)]).
precondition(perform_abdominal_thrusts, [retilt(head), given('first pair of breaths')]).
precondition(perform_finger_sweep, [performed('abdominal thrusts')]).
precondition(perform_emergency_breathing,
    [unconscious(victim), observed('victim not breathing'), observed(pulse)]).
precondition(perform_three_compression_breathing_cycles,
    [performed('fifteen compressions'), given('second pair of breaths')]).
precondition(phone_paramedic, [unavailable(assistance), temporarily_stopped(cpr)]).
precondition(stop_bleeding, [bleeding(victim)]).
precondition(yell_for_help, []).
```

Figure 4.2 CPR Tutor Sample Preconditions

---

[4]See also Appendix D.

and deletepostconditions. The basic format of each is similar to that for preconditions:

addpostcondition(<operator>,[<assert-fact1>,<assert-fact2>,...]).

deletepostcondition(<operator>,[<delete-fact1>,<delete-fact2>,...]).

Real world applications, however, are not always so cut-and-dried. In many applications, including CPR, the same operator can have different effects in different circumstances. An example is the application of the operator *give breaths*. This operator is applied numerous times in the the process of providing CPR. It is necessary to assert which iteration of *give breaths* has been applied each time the operator is employed. To allow this flexibility, multiple three-argument postcondition predicates can be used for applicable operators, in addition to the standard two argument format.[5] The format of this three-argument form is:

addpostcondition(<operator>,[<prereq-fact1ist>],[<assert-factiist>]).

deletepostcondition(<operator>,[<prereq-fact1ist>],[<delete-factlist>]).

Figure 4.3 contains a sampling of the various two and three-argument postcondition facts used in the CPR Tutor.

To more accurately reflect real-life circumstances it necessary to allow the possibility of randomness. For example, when the rescuer checks the victim's pulse, a pulse may or may not be present. Thus, although each operator has obligatory postcondition facts, other facts can be deleted and/or inserted in the new state through the

[5]This enhancement was developed by Professor Rowe to allow increased flexibility.

```
deletepostcondition(open_airway, []).
addpostcondition(open_airway, [open(airway)]).

deletepostcondition(perform_emergency_breathing, [observed(pulse)]).
addpostcondition(perform_emergency_breathing,
   [given('first pair of breaths')], [observed('no pulse')]).
addpostcondition(perform_emergency_breathing,
   [not(given('first pair of breaths'))], [still_no_pulse]).
addpostcondition(perform_emergency_breathing,
   [error-in-perform-emergency-breathing]).

   [performed('fifteen compressions'), given('second pair of breaths')]).
addpostcondition(perform_three_compression_breathing_cycles,
   [performed('compression breathing cycles')]).

deletepostcondition(give_two_breaths,
  [stopped_breathing, performed('finger sweep')]).
addpostcondition(give_two_breaths,
   [phoned(paramedic), still_no_pulse],
   [given('sixth pair of breaths')]).
addpostcondition(give_two_breaths,
   [on_back(victim), open(airway), performed('fifteen compressions')],
   [given('second pair of breaths')]).
addpostcondition(give_two_breaths,
   [open(airway), on_back(victim), not(phoned(paramedic))],
   [given('first pair of breaths')]).
addpostcondition(give_two_breaths, [error-in-give-two-breaths]).

deletepostcondition(recheck_pulse, [phoned(paramedic)],
     [performed('compression breathing cycles')]).
deletepostcondition(recheck_pulse, []).
addpostcondition(recheck_pulse, [still_no_pulse]).
```

Figure 4.3 CPR Tutor Sample Postconditions

predicate **randsubst.**[6] The format for this predicate is as follows:

randsubst(<operator>,[[<delete-fact1>,<assert-fact1>,<probability1>,<optional-msg1>],

[delete-fact2>,<assert-fact2>,<probability2>,<optional-msg2>],...]).

Figure 4.4 contains a listing of the **randsubst** facts used in the CPR Tutor.

```
randsubst(check_pulse, [[observed('no pulse'), observed(pulse), 0.2]]).
randsubst(open_airway, [[unavailable(assistance), available(assistance), 0.3,
    'Someone has responded to your yell for help.']]).
randsubst(perform_emergency_breathing,
    [[unconscious(victim), unconscious(victim), 1.0,
    'The heart has stopped beating.  What should you do now?']]).
randsubst(position_victim, [[unavailable(assistance), available(assistance),
    0.3, 'Someone has responded to your yell for help.']]).
randsubst(standby_to_assist, [[observed('victim not breathing'),
    observed('victim not breathing'), 1.0,
    'Breathing has stopped.  What should you do now?']]).
randsubst(stop_bleeding, [[breathing(victim), observed('victim not breathing'),
    0.4, 'Bleeding is stopped.  However, the victim has stopped breathing.']]).
randsubst(yell_for_help,[[unavailable(assistance), available(assistance), 0.3,
    'Someone has responded to your yell for help.']]).
randsubst(give_two_breaths,
    [[given('first pair of breaths'), obstructed(airway), 0.3,
    'Airway is obstructed - you are unable to breathe air into the victim.']]).
```

Figure 4.4 CPR Tutor Random Substitutions

---

[6]This was an enhancement developed by Professor Rowe to allow for randomness.

C. KNOWLEDGE ACQUISITION

The CPR domain expertise was derived solely from a subset of the workbook material utilized by the American Red Cross to conduct formal CPR classes. Although this represents a reliance on a single expert instead of multiple experts as recommended, it was deemed adequate for the development of the CPR Tutor prototype. This decision was based on the prototypical nature of the CPR Tutor, the relatively limited length of available time for its development, and the fact that many medical experts were consulted in the formulation of the workbook itself. A operational version of the CPR Tutor, however, would benefit from the direct expertise of the actual medical experts.

Within the workbook, a skill test is provided which tests the student on their correct application of the CPR operators to a predefined scenario. This scenario unfolds as the student proceeds. For example, when the student performs the operator *check for breathlessness,* the instructor says "No breathing". The students acknowledges by repeating the phrase "No breathing".

Randomness, however, is not a factor in the American Red Cross skill test. The instructor does not, for example, arbitrarily select "No breathing" as opposed to "Breathing" as the response to give to the student. The direction is clearly defined by a script type format in which the instructor's response is given. For the development of the CPR Tutor, however, these junctures provided the most logical points for randomness. The expertise on how to respond to a direction other than the one taken in the skill test was derived from reading material provided elsewhere in the workbook and/or in the instructor's manual. For example, the skill test follows the assumption that someone else is available to assist the primary rescuer, i.e., the user of the CPR Tutor. Therefore, *instruct someone to phone paramedic* is one of the predefined operators that the student needs to perform to successfully pass the skill test. In textual material which follows the

skill test, the student is provided the information on what to do if no one responds the the rescuer's yell for help. It does not merely list operators which should be performed, but instead states the rescuer should perform CPR, i.e., compression-breathing cycles, for at least one minute prior to going to a phone themselves to call the paramedic. The rescuer should resume CPR as soon as possible thereafter [Ref. 1].

In transposing this expert knowledge into the means-ends analysis format required by the CPR Tutor, it was necessary to first define the applicable operators and their corresponding recommended, precondition, and postcondition facts. The process of creating these facts can perhaps best be explained by way of a couple examples.

One of the more straightforward operators was *open airway*. To open the victim's airway, it is physically necessary for the victim to be on their back. It is also not logical to perform this operator on anyone who is not unconscious. The precondition:

precondition(open_airway, [on_back(victim), unconscious(victim)]).

was used to capture these facts. Opening the airway does not delete any previously asserted facts, but its performance does presumably cause an open airway. Thus the following recommended and postcondition facts are applicable:

recommended([open(airway)],open_airway).

deletepostcondition(open_airway, []).

addpostcondition(open_airway, [open(airway)]).

Because this is one of the earliest operators performed, it is possible that someone could respond to the rescuer's earlier yell for help while this operator is being performed. With an assigned thirty percent probability of someone responding to the earlier yell for help

during the performance of the open airway operator, the following random substitution fact was created:

randsubst(open_airway, [[unavailable(assistance), available(assistance), 0.3, 'Someone has responded to your yell for help.']]).

When randomness was employed, complications in defining the means-ends analysis facts arose. For example, if assistance is available, this other person should be instructed to phone the paramedic after the victim's pulse has been checked and prior to the rescuer locating the compression position. This implied that a fact such as *help is phoned* should be a precondition for the compression position being located. However, this could not be the case because, if help did not respond, the *help is phoned* fact would not be applicable. In fact, it would be a wrong action on the student's part. Therefore, the precondition:

precondition(locate_compression_position, [observed('no pulse'), observed('victim not breathing'), not(available(assistance))]).

was used. The fact *not(available(assistance))* was used to represent the fact that help, if previously available, was no longer available at that point because the available assistant had left to phone the paramedic. This was a result of the deletepostcondition fact associated with the operator *instruct someone to phone paramedic*. If help had never responded to the *yell for help* operator, the precondition would also be met.

Thus, in representing the knowledge contained in the American Red Cross CPR workbook [Ref. 1], similar assignments were made for each of the operators. Some proved to be very straightforward in their translation into means-ends analysis facts.

Others, however, required adjustments in the code from what originally might have seemed sufficient. This was directly attributable to the implementation of randomness.

D. TUTOR MODULE

The tutor module[7] represents a distinguishing feature of ICAI systems over the more traditional CBI approach, in that the teaching strategies are separated from the expert knowledge base. In the CPR Tutor prototype, the tutor module is basically a stand-alone system which could be utilized to tutor any domain which can be represented as a search problem for means-ends analysis. For example, a more general version of this same tutor has been used to provide training to a Navy fire team leader in combatting a fire aboard a Navy vessel.

The purpose of the tutor module is to monitor the status of the student model and thus guide the course of future dialogue between the ICAI system for CPR and the user. To meet this purpose, it is necessary for the inclusion of information about effective teaching strategies in the tutor module. The tutoring rules used in this module are handled by the five argument predicate **handle_student_op**. The major tutoring strategies used by CPR Tutor include the following:

- **OK.**
  Reflects that the student's response matches that of the expert. This is used for identical matches as well as **nopref** conditions.
- **The operator you now need to perform is: <operator>.**
  This prompt is given in response to the user's request for help.
- **<Warning message>** presented on a cleared screen.
  A serious infraction on the user's part results in a specific warning message.

---

[7]The tutor module is implemented by the *metutor* program developed by Professor Rowe. It is contained in Appendix E.

- **<Warning message>** presented on the same screen.
  A less serious infraction on the user's part results in a specific warning message.
- **That operator requires that** <required preconditions list>.
  Indicates a mandatory precondition must first be satisfied before the operator can be applied. This violation is less severe than the above two cases.
- **That will not affect anything.**
  The action chosen by the student will have no affect on the current state nor on the overall solution.
- **That does not seem immediately helpful, but I will try it.**
  Allows the user to pursue their selected solution path.
- **I will try it, but it is not recommended or need for the problem.**
  Allows the student to apply an operator even though the system sees no need.

A central issue involved with the use of these tutoring strategies is the appropriateness of providing immediate responses to the user's action as compared with temporarily allowing the student to continue down an incorrect path without interruption. In many application areas, several solution paths may exist. The CPR procedure, however, is not loosely ordered. Much medical research has been conducted in determining the optimal ordering of operators. Although deviations from this order may not cause serious negative results, the incorrect ordering may, in fact, render the efforts of the rescuer ineffective. The CPR Tutor, therefore, is typically very stringent in the requirement that operators be performed in a specified order; students are not allowed to deviate to any great extent. It should be noted that this restrictive nature is not invoked by the tutor module itself, but rather by the CPR knowledge utilized by the tutor. When necessary to allow the student the option of choosing either of the two operators, the two argument predicate **nopref** is used. This is used in the CPR Tutor in the selection of the first two operators; represented by the Prolog fact:

nopref(check_if_unconscious,yell_for_help).

E. STUDENT MODEL

The student model is a representation of the student's understanding of CPR procedures as perceived by the CPR Tutor system. It is thus a model of the system's knowledge of the student based on their response to the specific situational state presented to the student. It is constructed by comparing the student's response to the expert module's means-ends analysis recommended response. The model is updated throughout the tutoring session.

Ingrained in the *metutor* program developed by Professor Rowe is a dynamic student model: a stack representation of the applied operators. Throughout the tutoring session, it was the current version of this stack which was used by the means-ends analysis subprogram to determine the tutoring strategy to be used. By analyzing the stack, a theory was developed as to what the student was actually trying to do. Although the human mental process isn't normally thought of in terms of stacks, it often seems like such a structure is used in the planning of complicated problems. The use of stacks in modeling the student was a subtle, yet complicated process.

A second use of the student model was much less complicated. It involved the creation of lists which captured the process used by the student. These lists were presented to the user at the completion of each tutoring session. They include a list of all the operators chosen by the user throughout the session, the operators for which the user requested help, and the operators which the user had difficulty in applying. Additionally, the student's total response time was calculated. This was kept for two purposes. One was to enforce some sense of urgency in knowing what do in each situation. The second was to present a relative overall response time measurement indicator to the user at the completion of the session. As such, diagnostics were provided to the user from which they could analyze their demonstrated misunderstandings. This self analysis approach

was used rather than a "score" because the author felt the domain of CPR, a life-or-death matter, should not be measured in terms of partial correctness. A detailed description of the specific diagnostics presented to the user are discussed later in this chapter in the user interface section.

F. USER INTERFACE

1. Input

The CPR Tutor prototype uses primarily a menu-based approach to obtain user input. The spcifice menus presented to the user are dependent on the experience level chosen, i.e., novice, intermediate, advanced.

a. Menu Advantages

Menus offer some primary advantages in their use. Firstly, an easy way is provided for the user to enter such data as user-experience level and desired-system option, i.e., HELP, Review CPR procedures, CPR skill test and QUIT. Subsequently, menus allow the user to easily interact with CPR Tutor, entering their recommended operator to the given state in the scenario.

Menus have the advantage of being especially easy to use for slow and/or inaccurate typists. There exists a lesser chance for typographical error and a resultant misrecognition by the system of the user's intended response. By being easy to use and self-explanatory by their very nature, the student's energy can be directed at learning the CPR procedure and not at how to use the system itself.

b. Menu Disadvantages

A primary disadvantage of menus is their restrictive nature. Users are not free to enter anything; their choice must be one of the menu items. The use of natural language input would seem to be a more natural and less restrictive form of communication for the user. Although natural language may ultimately provide the best

form for user input, it does not come without a cost. The use of natural languages in AI applications is a research area unto itself. Due to the inherent complexities and resource requirements of implementing a natural language input into the CPR Tutor prototype, this option was discarded for the most part. An exception is the pseudo natural language input option provided to the user of entering *help* or *quit* in lieu of a CPR operator. These options will be discussed later in this chapter.

c. Application

After the initial display which offers a Prolog reminder that all entries must be followed by a period, the user is prompted to enter their name. The main menu, displayed in Figure 4.5, is then presented, offering the user the option of requesting help, reviewing the major steps involved in providing CPR, testing their knowledge about CPR procedures, or terminating the session. Upon selecting item three of the main menu, *CPR skill test,* the major files are consulted and the user is then prompted via a menu to enter

---

```

|: 3.
```

Figure 4.5 CPR Tutor Main Menu

---

their experience level. The three choices are: Novice, Intermediate, and Advanced. Subsequent menu displays are based upon this selection.

At every step in the simulation, the Novice user is presented a menu of five possible operators, one of which is always preferred. By limiting the possibilities for selection, the Novice user has a greater chance of chosing the recommended operator. The user enters the number corresponding to their choice. A validation routine is used to ensure the user's input is within the range of one to five or is either "help" or "quit". A sample Novice user menu is displayed in Figure 4.6.

The menu presented to the intermediate user is an expansion of the one presented to the novice user: fifteen possible operators are provided. Again, the recommended operator is always present in the menu. The dictating criteria for

---

POSSIBLE OPERATORS ARE:

1. check_if_unconscious
2. recheck_pulse
3. instruct_someone_to_phone_paramedic
4. position_victim
5. yell_for_help

****
The following facts are now true:
assistance is unavailable, "help" is yelled, and victim is unconscious.
What operator do you choose? 1.

That will not affect anything.

Figure 4.6 Novice User Menu

---

providing fifteen instead of all twenty-one possible operators was based on human factors: the physical size of the screen did not allow all twenty-one operators, as well as the state summation, to be viewed simultaneously. The deletion of the remaining six operators in the menu was viewed as relatively insignificant. A sample intermediate user menu is displayed in Figure 4.7.

POSSIBLE OPERATORS ARE:

1. check_if_breathing
2. check_if_unconscious
3. check_pulse
4. recheck_pulse
5. give_two_breaths
6. instruct_someone_to_phone_paramedic
7. open_airway
8. perform_emergency_breathing
9. perform_fifteen_compressions
10. perform_three_compression_breathing_cycles
11. position_victim
12. retilt_head
13. stop_bleeding
14. temporarily_stop_cpr
15. yell_for_help

****

The following facts are now true:
victim is on_back, victim is bleeding, victim is unconscious,
and assistance is available.
What operator do you choose? 13.

YOU MUST be primarily concerned with the pulse and breath of the victim!!!
You must temporarily ignore any injuries.

Figure 4.7 Intermediate User Menu

To provide a more challenging environment to the advanced user, a different approach was used. To increase the number of possible operators by an order of magnitude, operator phrases were no longer utilized in the menu. Instead, all operators are broken down into two parts The user enters their selection by forming a phrase consisting of one verb and one noun phrase. To ensure distinction between the two parts of the phrase, the menu is comprised of two distinct columns. The advanced user menu is displayed in Figure 4.8.

POSSIBLE CHOICES FOR OPERATOR SELECTION ARE:

1.	check	a.	abdominal thrusts
2.	give	b.	airway
3.	instruct	c.	breathing
4.	locate	d.	breaths
5.	open	e.	compression breathing cycle(s)
6.	perform	f.	compression position
7.	phone	g.	compressions
8.	position	h.	emergency breathing
9.	recheck	i.	finger sweep
10.	retilt	j.	head
11.	stop	k.	"help"
12.	standby	l.	paramedic
13.	yell	m.	someone to phone paramedic
		n.	to assist if necessary
		o.	unconsciousness

****

The following facts are now true:
victim is bleeding and victim is unconscious.
What operator do you choose? [1,c].

That operator requires that victim must be on_back and airway must be open.

Figure 4.8 Advanced User Menu

An additional menu is presented to the advanced user to obtain a specific number of repetitions for some operators. This menu is displayed in Figure 4.9.

2. Output

The primary purpose of the prototype's output was threefold. Firstly, the CPR Tutor describes the situation at every step. Each phrase in the description is a list of facts and is referred to as the **state**. This state summation is provided to the user following the

---

Your selection: give breaths

Enter the NUMBER of times the operator should be performed.

- O R -

Select from the following by entering the appropriate letter:
a. temporarily
b. forever
c. until no longer necessary, rechecking pulse every few minutes
d. 2 to 3
e. 6 to 10
f. 7 to 15

ENTER YOUR CHOICE: 2.
That operator requires that victim not breathing must be observed.

Figure 4.9 Repetition Qualifier Menu for the Advanced User

---

menu of possible operators. A natural language transcriber[8] is used to change Prolog facts into more easily readable phrases.

The second, and perhaps the most important purpose, is the system's tutorial response to the action recommended by the user. A description of these messages is in the explanation of the tutor module given above.

A third output generator is a summarizer of the user session upon successfully reaching the goal state. This summation includes a full list of user actions followed by one of more of the following:[9]

- **Operators the user had difficulty in applying.** This list is comprised of operators which were the recommended operator for a given state but were not selected by the user.
- **Operators incorrectly applied.** This list is comprised of operators which were chosen by the user as being the correct response to a given state but differed from the expert's choice.
- **Operators in which the number of repetitions was incorrectly identified by the user.** This list is only applicable to the advanced user and is discussed above.
- **Operators for which the user requested help.** This list is comprised of all operators which were the applicable response when the user entered "help" in lieu of selecting a menu item.

The summation is concluded with the user's elapsed time in completing the session. The time includes everything following the completion of the display of the menu and the input of the user's response.

---

[8]This was written by Professor Rowe of the Naval Postgraduate School and is contained in the file *metutor* contained in Appendix E.

[9]See Appendix A through C for sample session summations.

V. SYSTEM USE

A. RESOURCE REQUIREMENTS

1. System Requirements

The CPR Tutor was developed and implemented on a Digital Equipment Corporation VAX 11/780 minicomputer running the UNIX operating system. This prototype is composed of seven files: *cpr, mecpr, metutor, utilities, actions, help and quit.* Together, these files require 68K bytes of memory. Of these files, the latter three are not critical to the successful operation of the system.

2. Program Language

CPR Tutor was implemented in Prolog, a general-purpose computer programming language. The specific version utilized was C-Prolog, a Prolog interpreter written in C, developed at the University of Edinburgh [Ref. 13].

B. DEMONSTRATION

Appendix A contains a demonstration of a CPR Tutor session with a novice, first-time user. Following the suggestion of the screen prompt, the student chose to review the help file and then opted to receive an overview of the major steps involved in the CPR procedure. Appendix B contains a demonstration of a CPR Tutor session with an intermediate user. Appendix C contains a demonstration of an advanced user's session with the CPR Tutor in which the number of operator options is increased to 390.

C. LIMITATIONS

1. Realistic Simulation

An inherent limitation of the CPR Tutor system is the significant difference between its environment and that of the actual performance of CPR procedures. An important part of training is obtainable only through actual physical practice on a specially designed manikin. However, the CPR Tutor can fully test the student on their procedural knowledge. The measuring of the student's response time was designed to instill a sense of urgency, albeit a far cry from a actual human being in need of CPR to save their life.

2. Accuracy

a. Parallelism

The CPR Tutor expert module contains the knowledge base for the system. Through manipulation of the data base by the tutor module the "expert's" recommended order of CPR operators is derived. As such, the student's actions are compared to a small number of recommended solution paths. The **nopref** predicate allows two successive operators in the student's path to be applied in interchangeable order. However, it is not possible to simultaneously apply two or more operators; this restricts the system. Although not extremely affected by this restriction, the CPR process does have two operators that should be possible to perform in parallel: *check if unconscious* and *yell for help*. Application domains which require parallelism in the application of operators can not be accurately implemented.

b. Careless Errors

By using a menu-based approach in the User Interface, specifically the input portion, it is felt careless typographical errors were diminished to a considerable extent. However, when input is via a computer keyboard, typographical errors can never be totally eliminated. Validation routines were used to ensure correct format utilization

by the user and were used to ensure the user's entry was within the acceptable range. Beyond these constraints, however, there is no prevention from a student carelessly entering a wrong choice, i.e., not their actual choice, yet still an acceptable input or simply a quick input with no thought process behind it. This may require several extra responses on the student's part to return to the correct solution path and their total response time and session summary report will reflect this.

D. RECOMMENDED SYSTEM ENHANCEMENTS

1. Operator Selection

More depth in the training could be achieved by querying the user on the actual process used in applying each operator. For example, the user must locate the compression position prior to performing chest compressions. Although the user is tested on their knowledge of when to locate the position, they are not tested on actually locating the position. The further breakdown of each operator therefore represents a possibility for expanding the training capabilities of the CPR Tutor. The file *actions,* although not fully implemented, represents a start at this enhancement.

The difficulty level could easily be increased for the advanced user with the addition of more operators associated with more complex scenarios. For example, a situation could be presented in which multiple victims are present and it is first necessary for the rescuer to determine the victim in most critical need of medical attention.

2. Student Modeling

The dynamic model of the student developed by the *metutor* program utilized a stack to record the actions of the student. From an analysis of the student model, the general tutoring methodology to be used was determined. The tutor, in following a particular approach, would present to the user a message such as "That will not affect anything" as an indicator of how the system perceived the effectiveness of the student's

action. However, this approach does not attempt to reason why the student chose the operator they did. This approach would represent an enhancement.

3. Biased Randomness

The CPR Tutor currently is developed to use predefined probabilities to generate randomness. To change the assigned probabilities, it is necessary to modify the code contained the the *mecpr* file. While this is very easy to do, it is not practical for the average user. A recommended enhancement would be the use of the student model to dynamically modify these probabilities. With this enhancement, a student having difficulty with a particular area could be presented with more situations in which this defective area is relevant. As such, the student would be given more opportunities to overcome their weaknesses. Similarly, permanent storage could be used to record each user's session; information could then be gathered from previous sessions as well as the current one.

4. Graphics

The CPR Tutor strictly used a verbal "conversation" with the student. As such, the system actually related to the student the relevant facts. A more realistic approach would be to use graphics to pictorially display what is occurring. It would then be up to the student to discern the relevant facts from their own direct visual observation of the situation, the same as is necessary in real-life situations.

5. Portability

With rapidly improving technology, the possibility does exist to implement the CPR Tutor or similar system on an easily accessible microcomputer. Two possible versions of Prolog which are now available for microcomputers are Micro-Prolog and Turbo-Prolog.

VI. SUMMARY

This study was undertaken to determine the feasibility of developing and implementing an ICAI prototype system for CPR. It is not a full-scale production model. As a prototype, limitations in the system's capability were expected. The majority of these limitations were a result of the relatively limited amount of time spent in design, development and implementation of the CPR Tutor prototype. Whereas many ICAI projects are ongoing for years, by a team of researchers, the entire CPR Tutor project was completed in less than one year.

In answer to the basic research question addressed by this study, i.e., the feasibility of implementing an effective, efficient, and challenging ICAI system for the purpose of providing CPR training, the author clearly feels the answer is unequivocally "yes". In answer to the question concerning the means that should be utilized in developing such a system, the means-ends analysis tutorial approach seems effective. The CPR procedure could cleanly be decomposed into abstractions. Clear and orthogonal operators could be identified as well as the corresponding preconditions and postconditions. This is not to say, however, that other approaches might not have also been effective.

C P R

One out of every two people in the United States can expect to die from a heart attack or a related disease or failure. The American Red Cross offers adult CPR courses in an effort to reduce this drastic death toll.

This CPR Tutor is designed to help maintain your level of proficiency in knowing how to provide CPR treatment at the scene of an emergency. Based upon your level of experience, you will be prompted by the tutor for your response when confronted with the current state of the emergency.

ENTER any letter key to continue: f.

##################### { Next Screen Display } #####################

NOVICE

As a novice user you will be given a list of 5 possible operators, one of which is the correct response.

INTERMEDIATE

As an intermediate user you will be given a list of 15 possible operators, one of which is the correct response.

ADVANCED

As an advanced user you will be presented with two columns. Your response will be a selection of a number from column one and a letter from column two in the format "[#,letter]" such that a phrase representing the opertor will be formed.

ENTER any letter to continue: c.

###################### { Next Screen Display } ######################

HELP

At any time you are unsure of the correct response and desire help you can enter "help." or simply "h.". This will prompt the tutor to give you the preferred response.

QUIT

At the end of each session you will be provided a summary of your actions. If you desire to end a session prior to the logical completion, entering "quit." will abort the program and return you to the system prompt. No summary of the aborted session will be provided.

ENTER any letter key to return to main menu: t.

CPR OVERVIEW - MAJOR STEPS

1. Check if unconscious.
2. Yell for help.
3. Position victim.
4. Open airway.
5. Check if breathing.
6. Give two full breaths.
7. Check pulse.
8. Instruct someone to phone paramedic - if assistance is available.
9. Locate compression position.
10. Perform 15 compressions.
11. Give two full breaths.
12. Perform 3 compression/breathing cycles.
13. Recheck pulse.
14. Temporarily cease cpr to phone paramedic - if phonecall not already made.
15. Give two full breaths.
16. Perform compression_breathing cycles until no longer applicable.

The following facts are now true:
victim is on_back, victim is bleeding, victim is unconscious,
 and assistance is available.
What operator do you choose? 13.
YOU MUST be primarily concerned with the pulse and breath of the victim!!!
You must temporarily ignore any injuries.

@@

It is important that you check the cartoid pulse for 5 to 10 seconds before starting CPR.

IT IS DANGEROUS TO PERFORM CHEST COMPRESSIONS IF THE HEART IS BEATING.

The operators you had difficulty in applying were:
   instruct_someone_to_phone_paramedic

The operators you incorrectly applied were:
   temporarily_stop_cpr

The operators for which you requested help were:
   instruct_someone_to_phone_paramedic

Your total time for responses was 6 minutes, 16 seconds.
This equates to an average response time of 14 seconds per question.

/*************************************************************************/

  1. Load prolog with increased parameters:
     /usr/local/prolog -a 500 -g 500 -h 500
  2. Load the file "CPR" by typing [cpr].

  The following files are required:
     metutor
     mecpr
     utilities
     actions
     quit
     help
     datetemp

  CPR will take control and automatically begin execution of the tutor
